

C Programming Introduction

Week 5:Expressions

Dept of Software Engineering Hanoi University of Technology

For HEDSPI Project

Topic of this week

- Expressions
 - Class Lecture Review
 - mathematic operators
 - boolean operators
 - conditional expressions
 - Programming Exercises

```
    Arithmetic Operators
```

```
Addition
Subtraction
Multiplication
Division
Modulation
Example
fag = x % y;
c = a - (a/b)*b;
```

- sum = var1 + var2 + var3;

Expression and Operations

- Operator precedence
 - Some arithmetic operators act before others (i.e., multiplication before addition)
 - Use parenthesis when needed
 - Example: Find the average of three variables a, b and c

```
• Do not use: a + b + c / 3
```

• Use: (a + b + c) / 3

Rules of operator precedence:

Operator(s)	Operation(s)	Order of evaluation (precedence)	
()	Parentheses	Evaluated first. If the parentheses are nested, the expression in the innermost pair is evaluated first. If there are several pairs of parentheses "on the same level" (i.e., not nested), they are evaluated left to right.	
*, /, or %	Multiplication Division Modulus	Evaluated second. If there are several, they re evaluated left to right.	
+ or -	Addition Subtraction	Evaluated last. If there are several, they are evaluated left to right.	

Decision Making: Equality and Relational Operators

- Executable statements
 - Perform actions (calculations, input/output of data)
 - Perform decisions
 - May want to print "pass" or "fail" given the value of a test grade
- if control structure
 - Simple version in this section, more detail later
 - If a condition is true, then the body of the if statement executed
 - 0 is false, non-zero is true
 - Control always resumes after the if structure
- Keywords
 - Special words reserved for C
 - Cannot be used as identifiers or variable names

Decision Making: Equality and Relational Operators

- Relational Operators
 - Less than
- <
- a < 5
- Less than or equal <=</p>
- a <= b

More than

- a > b + c
- More than or equal>=
- a >= b + 5

- Equal

- a == -6
- Not equal
- =
- a != 0

Decision Making: Equality and Relational Operators

Keywords			
auto	double	int	struct
break	else	long	switch
case	enum	register	typedef
char	extern	return	union
const	float	short	unsigned
continue	for	signed	void
default	goto	sizeof	volatile
do	if	static	while

```
· Using if statements, relational Example 1
2 #include <stdio.h>
4 int main()
6
     int num1, num2;
8
     printf( "Enter two integers, and I will tell you\n" );
     printf( "the relationships they satisfy: " );
   scanf( "%d%d", &num1, &num2 ); /* read two integers */
10
11
12
    if ( num1 == num2 )
13
      printf( "%d is equal to %d\n", num1, num2 );
14
15
     if ( num1 != num2 )
16
      printf( "%d is not equal to %d\n", num1, num2 );
17
18
    if ( num1 < num2 )</pre>
19
       printf( "%d is less than %d\n", num1, num2 );
20
21
   if ( num1 > num2 )
22
      printf( "%d is greater than %d\n", num1, num2 );
23
24
    if ( num1 <= num2 )</pre>
25
        printf( "%d is less than or equal to %d\n",
               <u>num1, num2);</u>
```

```
27
28
      if ( num1 >= num2 )
29
           printf( "%d is greater than or equal to %d\n",
30
                      num1, num2);
31
32
      return 0;  /* indicate program ended successfully */
33 }
Enter two integers, and I will tell you
the relationships they satisfy: 3 7
3 is not equal to 7
3 is less than 7
3 is less than or equal to 7
Enter two integers, and I will tell you
the relationships they satisfy: 22 12
22 is not equal to 12
22 is greater than 12
22 is greater than or equal to 12
```

Logical Operators

Expression and Operations

Bitwise Operators

 $-x ^ y = 01100111x << 2 = 00101100$

```
Assignment Operators and Expressions

op is + - * / % << >> & ^
If expr1 and expr2 are expressions, then
expr1 op= expr2

Equivalent to

expr1 = (expr1) op (expr2)

Example

X += 1;
X = X + 1;

Equivalent

Eq
```

Expression and Operations

Conditional Expressions

```
expr1 ? expr2 : expr3

- If expr1 is true do expr2
- If expr1 is false do expr3

• Example
- a = 5;
b = 10;
min = a < b ? a : b;</pre>
```

- Increment and Decrement Operators
 - Pre-increment operation
 Post-increment operation
 Pre-decrement operation
 Pre-decrement operation
 - Post-decrement operation
 variable
- Example

Expression and Operations

Type Cast Operator (Casting)

```
(type-specifier) expression;
```

- Example

Exercise 5.1

- Write a program that converts distances from kilometers to miles.
- Ask user to input the kilometers value then output to screen the miles value.

Exercise 5.2

- Run the exercise5_2.c program below to illustrate the operation of Logical operators and relational operators.
- Replace b a == b c by a = b-c
 and then explane the result.

Exercise 5.3

- Type and compile the exercise5_3.c below, the program illustrates the operation of conditional expressions.
- Alter the program by eliminating the abs and max variables.

Exercise 5.4

- This example illustrates the integer overflow that occurs when an arithmetic operation attempts to create a numeric value that is larger than can be represented.
- Type and compile the program to see the result.

Exercise 5.5

- Write a program that requires user to input two double values stored in two variables x,y.
- Use if control structure to examine all the relation between x and y.

Exercise 5.6

- A group of n students is to be divided into 7 classes, as evenly as possible. (No class size should differ by more than 1 student when compared to all other class sizes.) Write a C expression for:
 - the number of students in the smallest class
 - the number of students in the largest class
 - + the average number of students per class;
 - the number of classes of above average size;
 - the number of classes of at most average size;
 - the number of students in classes of larger than average size;
 - the number of classes of exactly average size.
